

Application enclaves & secure communication. Trust is established through (remote) attestation of interacting components. Local communication (between enclaves on the same processor) is secured but not depicted in this illustration. To provide availability guarantees (e.g. for AppA), a protected scheduler enclave needs to be added to the Sancus nodes.

Untrusted components

Malicious interactions or bugs in untrusted code do not harm security but may, on some platforms, harm availability or lead to resource exhaustion.
